***Abstract:*** *The estrogen receptor alpha (ERα) plays an important role in breast development and pro-proliferation signal activation in the normal and cancerous breast. The ERα inhibitors were potentially active as cytotoxic agents against breast cancer. This study was conducted in order to find Asymmetrical Hexahydro-2H-Indazole Analogs of Curcumin (AIACs) as hits of ERα inhibitor. A training set of 17 selected ERα inhibitors was used to create 10 pharmacophore models using LigandScout 4.2. The pharmacophore models were validated using 383 active compounds as positive data and 20674 decoys as negative data obtained from DUD.E. Model 2 was found as the best pharmacophore model and consisted of three types of pharmacophore features, viz. one hydrophobic, one hydrogen bond acceptor, and aromatic interactions. Model 2 was utilized for ligand-based virtual screening 186 of AIACs, AMACs, intermediates, and Mannich base derivative compounds. The hits obtained were further screened using molecular docking, analyzed using drug scan, and tested for its synthesis accessibility. Fourteen compounds were fulfilled as hits in pharmacophore modeling, in which 10 hits were selected by molecular docking, but only seven hits met Lipinski's rule of five and had medium synthesis accessibility. In conclusion, seven compounds were suggested to be potentially active as ERα inhibitors and deserve to be synthesized and further investigated.*

## ■ INTRODUCTION

Breast cancer is a disease that occurs almost entirely in women. It is the second leading cause of death by a disease [1]. In 2018, 2.1 million new cases of breast cancer were found. In most countries, this disease was the most commonly diagnosed cancer (154 out of 185) [2]. The estrogen receptor alpha (ERα) plays a role in breast development and the activation of the pro-proliferation signal in normal and cancerous breasts [3]. The growth of breast cancer cells is characterized by the high expression of the receptors [4]. Nowadays, ERα has been developed and tested as molecular targets for the treatment and prevention of breast cancer [5].

Monocarbonyl Analogs of Curcumin (MACs) and Asymmetrical Monocarbonyl Analogs of Curcumin (AMACs) were reported to show better inhibition against cancer cell proliferation of SMMC-7221, MCF-7, and PC-3 compared to curcumin [6]. Diethylamine Mannich base substitution of the phenyl ring of MACs showed increased activity and selectivity of its anticancer properties [7]. Mannich base substitution of AMACs

also showed cytotoxicity potential against HeLa, MCF-7, and WiDr cells [8-9]. The Mannich base acted as an important pharmacophore group in high-potential drugs [10].

Several studies reported that structural modification of symmetrical MACs into symmetrical Hexahydro-2H-Indazole Analog (IAC) exhibited good antioxidant and antitumor activity against Hep G2, WI38, VERO, and MCF-7 cells [11-12]. Some studies also reported that modified compounds with indazole group formation show better anticancer activity [13-14]. However, to the best of our knowledge, there were no reports about the development of AMACs into AIACs and its derivatives. In the present study, we designed 186 structures of AIACs, their derivatives, and intermediate compounds that have different substituents in one of the benzene rings.

In this study, the initial virtual screening of 186 ligand designs was carried out using the Ligand-based virtual screening (LBVS) method. The LBVS methods compare a library of compounds with a known active ligand. Two notable advantages of LBVS methods are that they do not require structural information of a target receptor and that they are faster than structure-based methods [15]. The objective of the study was to discover a new molecular entity of AIACs compounds as hits for ERα inhibitor. The 186 AIACs, AMACs, intermediates, and the Mannich base derivative compounds were screened virtually through ligand-based pharmacophore modeling, structure-based molecular docking, analysis by drug scan, and tested for its synthesis accessibility.

## ■ COMPUTATIONAL METHODS

### Equipment

The hardware used for the calculations, pharmacophore modeling, and molecular docking was a laptop with the following specification: Desktop-AF57S8U, Processor Intel(R) Core(TM) i5-5200 CPU@ 2.20 GHz 2.20 GHz, RAM 16 GB, Operating System Windows 10, 64 bit, Graphic Card AMD Radeon R9-M275 4GB. The software used includes Marvinsketch, LigandScout 4.2, and AutoDockTools (v 4.2) integrated LigandScout software 4.2.

### Procedure

#### *Data preparation*

The 186 compounds of Asymmetrical Hexahydro-2H-Indazole Analogs of Curcumin (AIACs), AMACs, its intermediate, and Mannich base derivatives were drawn using Marvinsketch (www.chemaxon.com). The structures are shown in Table S1.a–g. A set of data of 34 ERα inhibitor compounds (Table S2.a–b) that consists of four native ligands of ER PDB and 30 other compounds with $pIC_{50}$ values in the range of 4.40 to 9.86, were obtained from www.pubchem.com. The three-dimensional (3D) Estrogen Homo sapiens receptor alpha (ERα) in the complex with E4D600 ligands (PDB code: 1SJ0) was obtained online from a database: NCBI, Research Collaboratory for Structural Bioinformatics Protein Data Bank http://www.pdb.org/pdb/home/ [9,16].

#### *Pharmacophore models preparation and validation*

The pharmacophore models were created using LigandScout4.2 [17]. A set of data of 34 ERα inhibitor compounds were grouped according to their cluster of chemical structure similarity. Every cluster of the compounds found was divided in the same proportion randomly to obtain two groups that consist of 17 molecules of ERα inhibitors. Seventeen selected molecules were used as a training set to create ten pharmacophore models. The 383 active compounds and 20674 decoys were used as positive and negative data to validate the pharmacophore models and determine the best pharmacophore model. The validation parameter of the receiver operating characteristic (ROC) that consisted of areas under the curves (AUC 100%) and enrichment factors (EF 1%) was calculated to determine the sensitivity, specificity, and accuracy values. The pharmacophore model with sensitivity > 0.5, specificity > 0.5, AUC value > 0.7, and a hit score > 0.7 was used as a virtual screening model [18].

#### *Ligand-based virtual screening*

The virtual screening was used to find AIACs compounds as hits of ERα inhibitors. A database of 186 AIACs and AMACs compounds in .mol file format was put in a screening database of a selected and validated pharmacophore model, then the screening process was

performed until completed. Tamoxifen was used as a positive control. The hit compounds obtained were further sorted based on the best pharmacophore fit values.

### *Molecular docking study*

Docking simulations were carried out to visualize molecular-level interactions between the hits obtained from ligand-based pharmacophore modeling with the active site of ERα (PDB code: 1SJ0) using tamoxifen as a positive control. The docking was done using AutoDock (v4.2) (autodock.scripps.edu/resources/autodock-force field) integrated with LigandScout. The method was validated by extracting the co-crystalline ligand (E4D600) from the ERα crystallographic structure and re-docking the copy of the ligand into its active site. The root-mean-square deviation (RMSD) value of the copy ligand conformation docked at the receptor as compared to the co-crystalline ligand conformation at the same receptor was calculated. The molecular docking was performed by running the Genetic Algorithm parameters 100 times, with algorithm generation number of 27,000, 2,500,000 energy evaluation numbers, and 150 population.

### *Drug scan and synthesis accessibility analysis*

The drug scan and synthesis accessibility were analyzed online on a website (http://swissadme.ch). The analysis involved uploading the ligand file in .smile format. Then, the results were downloaded in excel format.

## ■ RESULTS AND DISCUSSION

The asymmetrical hexahydro-2H-indazole curcumins (AIACs) were designed as the development of AMACs that refers to the modification of MACs into a symmetrical hexahydro-2H-indazole analog of curcumins (IACs) that provided good results for activity in several cancer cells including breast cancer cells [12]. The AMACs and derivatives exhibited cytotoxicity potential against HeLa, MCF-7, and WiDr cell lines [8-9], thus AIACs were also predicted to have cytotoxic activities as well. The structure of the designed AIACs (Table S1.c–f) had different substituents in one of the benzene rings (–H, –$CH_3$, –F, –Cl, –$OCH_3$, –dimethoxy) by considering their different characteristics of electronegativity, electronic charge, and induction effect of the substituents resulting in different geometric shapes for each analog compound. Therefore, the structures had variations in the bonding interactions with the receptors. In the present study, the AIACs were first screened virtually by ligand-based pharmacophore modeling. The hits obtained were then screened by structure-based modeling using molecular docking and further screened again by drug scan and synthesis accessibility analysis to obtain the new bioactive compounds as hits of ERα inhibitor.

Virtual screening (VS) has emerged as a crucial device in identifying bioactive compounds via computational means by employing knowledge on the protein target or known bioactive ligands [19]. Several VS with ERα as a protein target using the structure-based virtual screening (SBVS) protocol had been reported. The protocol screened compounds based on the interactions of the 3D structure of the compounds with the target protein [20-21]. In this study, before the compounds were screened with the SBVS protocol, the compounds were first screened using the LBVS protocol. The compounds were selected based on the similarity of the molecular structure (in terms of shape, pharmacophoric features, molecular fields, etc.), which was believed to show similar behavior. LBVS techniques that consist of substructure mining and fingerprint searches are faster than SBVS techniques (e.g., molecular docking) [22-24]. The benefit of combining docking primarily based digital screening with pharmacophore-primarily based digital screening is that the database of ligands can be pre-filtered by using a pharmacophore query, before assessment using docking simulations. The docking simulations can be published and filtered with the use of a pharmacophore question to dispose of any compounds that fail to bind consistently with the pharmacophore query. The pharmacophore version can in this case be used for the position of the ligand, in addition to the precision of a molecule towards the pharmacophore question; or to guide the placement via a constraint while scoring the extraordinary docking poses [25].

### Pharmacophore Model Preparation and Validation

The 3D pharmacophore of the various training sets produced 10 pharmacophore models. The validation of the models by a data set of 383 active compounds as

positive data and 20674 decoys as negative data produced hit scores in the range of 0.7679–0.7718 and three pharmacophore features marked by red, yellow, and purple for HBA, hydrophobic, and AR interaction, respectively. The HBA interaction was formed by the hydroxyl groups in the AR and the ether group; the hydrophobic interaction was formed by the AR, which also showed AR interactions. Fig. 1 presents the 3D pharmacophore model 2 with the type of features and distance between features. The 3D and 2D pharmacophores model of training set E4D600, is shown in Fig. 2, and the types of pharmacophore features marked by color differences in the training set compound are shown in Table 1. The ROC curve of model 2 is shown in Fig. 3. The screening of the ERα inhibitors using model 2 pharmacophore produced the best result in sensitivity = 0.687; specificity = 0.845; AUC 100% = 0.80; accuracy = 0.843; $EF_{1\%}$ = 26.7 and hit score = 0.7712. The set of five hypotheses with sensitivity > 0.5, specificity > 0.5, AUC value > 0.7, and hit score > 0.7 can be used as a virtual screening model [26]. The EF and AUC values showed that the virtual screening method using pharmacophore model 2 was an excellent screening model. The EF and AUC values were worse than the SBVS protocol reported by Yuniarti et al. [27], but it was still better than the results reported by Setiawati et al. [28], and also the EF and AUC values of the SBVS protocol used to identify ligands for ERα in DUD-E (EF = 15.4, AUC = 0.675) [29]. Therefore, the virtual screening of 186 AIACs and AMACs compounds was performed using model 2.

## Ligand-Based Virtual Screening

The key features of the pharmacophore interactions of tamoxifen on ERα were hydrophobic interactions, HBAs, and AR interactions (Fig. 1). The virtual screening of 186 AIACs and AMACs compounds resulted in 14 hit compounds that are shown in Table 2. The pharmacophore fit values measured geometric features of molecules for 3D structure-based pharmacophore models. The higher the pharmacophore fit values indicated the higher possibility of the hit to match with the pharmacophore model and show higher activity as ERα inhibitors. The pharmacophore fit values of 14 hits ranged from 45.32 to 53.43. Compounds 3B8,

3B10, and 3B7 had the best pharmacophore fit values as indicated by their chemical features that are in harmony with the features of the tamoxifen pharmacophore model. None of the hits were Mannich base derivatives. The result was different from the result of *in vitro* evaluation against MCF-7 cell lines of the Mannich base of AMACs reported previously (active but nonselective) [8-9].

## Molecular Docking

The structure of ERα in the complex with E4D600 ligands (PDB code: 1SJ0) was selected for in silico study because the parameters were suitable for experimental studies, with a resolution of 1.9 Å, free R-values of 0.272, and working R-values of 0.218. The R-value illustrates a measure of how well the enhanced structure predicts the

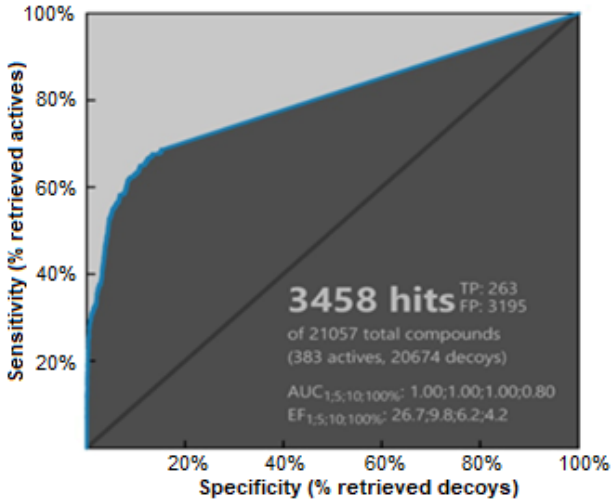

**Fig 3.** ROC curve model 2

observed data [30]. Interactions between co-crystalline ligand E4D600 with the active site of ERα were dominated by hydrophobic interactions with ARs, and hydrogen bonds with phenoxy and hydroxyl oxygen (Fig. 4 and 5). The best ligand-docking conformation is shown in Fig. 6. The RMSD value of the copy ligand-docking conformation in the active site of ERα compared to the co-crystalline ligand-docking conformation at the same receptor was 0.940 Å (< 2.0 Å), indicating the validity of the protocol.

The results of molecular docking of 14 hit compounds obtained from the ligand-based pharmacophore model are shown in Table 3. The free energy values, ΔG, of the 10 best hits (3A6, 3B1, 3B2, 3B3, 3B4 3B7, 3B8, 3B9, 3B10, and 3B11) did not differ significantly with that of tamoxifen. The interaction of amino acid residues with compounds 3B8 and 3B9 was 14 and 15. It was comparable with the interaction of amino acid with tamoxifen having 17 residues (Table S3 and Table 4). The hydrophobic interaction patterns of compounds 3B7, 3B8, 3B9, 3B10, and 3B11 showed similar triangular patterns and two little differences in the distance (Table S4 and Table 5).

## Drug Scan and Synthesis Accessibility Analysis

The drug scan and synthesis accessibility analysis of 10 hit compounds were performed using molecular docking study by running them in www.swissadme.ch. The results showed that seven compounds (3A6, 3B1, 3B2, 3B3, 3B4, 3B7, and 3B11) fulfilled Lipinski's Rule of Five (Table 6) and three compounds (3B8, 3B9, and 3B10) had log P values higher than other ligands (log P > 5), while the synthesis accessibility (SA) values ranged from 4.24 to 4.67. The molecular weights of the ligands were in the range of 334.41–444.95 g/mol which is higher than tamoxifen but still met Lipinski's Rule of Five (MW < 500 g/mol). The rule was a set of in silico guidelines applied to drug discovery to prioritize compounds with a

also be used to predict the pharmacokinetics of a compound as a drug candidate [33].

The SA values of the 10 hits ranged from 4.23 to 4.67, which indicated that the synthesis difficulty was medium and there were no differences among the compounds. However, compounds 3B1, 3B2, 3B3, and 3B4 with SA values in the range of 4.23–4.37 were easier to synthesize than the others. The SA values were based on the analysis of structural fragments of more than 13 million compounds, assuming that the more numerous the molecular fragments, the more difficult the molecules are to prepare. Descriptors correct this fragmental contribution method for molecular size and complexity and the SA values range from 1 (easily synthesized) to 10 (difficult to be synthesized) [34].

## ■ CONCLUSION

One hundred and eighty-six AIACs, AMACs, intermediates, and their Mannich base derivative compounds were successfully screened using ligand-based pharmacophore modeling, and the hits obtained were further screened using structure-based molecular docking in the active site of ERα, and were analyzed using drug scan and synthesis accessibility. Seven

compounds namely 3A6, 3B1, 3B2, 3B3, 3B4, 3B7, and 3B11 were suggested to be potentially active as ERα inhibitors and deserve to be synthesized and further investigated.
