ABSTRACT

Introduction: Geographic information system (GIS) can be very effective tool in combating dengue infection. However, there is only few study that apply GIS in dengue research in Indonesia

Objectives: The purpose of this literature review is to identify how geographic information system (GIS) applications have been used in dengue mapping in Indonesia and to critically examine the issues, strengths, weakness and challenges inherent to those approaches, especially from the spatial analysis and public health point of view.

Methods: The research articles in English or Indonesian were taken by online only using Google Scholar search engine. Only articles that addressed GIS methodology or dengue-related GIS applications were selected for this review. These articles must contain the combination three words including Geographic Information System (GIS), dengue and Indonesia in its titles or abstracts.

Results: Through the review process, conducted in October 2013, it is evident that the applications of GIS in dengue research can be generally categorized into four issues including dengue risk mapping and surveillance (n = 5), combined remote sensing-GIS (n = 4) web application (n = 2), and climatic and other associated factor with dengue (n = 3). This review explores how GIS approaches have been used to analyze the correlation of dengue incidences with environmental risk factor. GIS also used as a tool to improve dengue surveillance and outbreak management. This review also revealed the lack of GIS techniques using in Indonesian dengue research.

Conclusion: GIS-related methodological techniques and tools can be meaning fully applied in dengue research and management.

Keywords: Geographic Information System (GIS), dengue, Indonesia

INTISARI

Pendahuluan: Sistem informasi geografis (Geographic Information System/GIS) dapat menjadi alat yang sangat efektif dalam menanggulangi infeksi dengue. Namun, hanya sedikit yang menggunakan GIS dalam penelitian dengue di Indonesia

Tujuan: Tujuan dari tinjauan pustaka ini adalah untuk mengidentifikasi bagaimana aplikasi sistem informasi geografis (GIS) telah digunakan dalam pemetaan dengue di Indonesia dan untuk memeriksa secara kritis isu-isu, kekuatan, kelemahan dan tantangan yang terjadi akibat pendekatan- pendekatan tersebut, terutama dari pandangan analisis spasial dan kesehatan masyarakat.
**INTRODUCTION**

Dengue infection (both of dengue fever/DF and dengue hemorrhagic fever/DHF) is a significant and emerging health problem in Indonesia and other tropical countries. Dengue fever and the more lethal dengue hemorrhagic fever are mosquito-borne diseases. They are caused by flavivirus that is transmitted by infected *Aedes* mosquitoes. Two fifths of the world’s populations are at risk. Dengue vectors can breed in any small amount of water such as vases, flower pots, discarded containers, or used tires.

As a vector borne disease, dengue infection depends on environment factor. So it becomes importance to study the disease and other related factor to help health officer make decisions to reduce the incidence and severity of its outbreaks.

Geography and studies of human health and well-being have a long history. A classic example of the value of a geographically orientated in health studies is John Snow’s study of mapping the outbreak of cholera in London in the mid-19th century that revealed a clustering around a water pump. GIS or Geographic Information System is a geographic tool that can be applied to gain insight into the relationships between health outcomes and social, demographic, economic, and ecological variables.

GIS can be used to complement conventional ecological monitoring and modeling techniques, and provide means to portray complex relationships in the ecology of disease. In addition, the use of GIS to identify environmental features allows determination of risk factors and delimitation of areas at risk, permitting more rational allocation of resources for cost-effective control. Since 1996, GIS have been used in our territorial cross-sectional and longitudinal parasitological surveys in order to experiment new applications to plan sampling protocols and to display quickly, clearly, and analytically the spatial and/or temporal distribution of parasitological data.

In theory, GIS can be an effective tool in combating dengue infection, however, in...
practice there are many challenges to its successful use in Indonesia. The focus of this review is to provide some balance discussion about using GIS in dengue research in Indonesia. A review of this type is needed because much of the literature in this area is written by health or geography researcher only, without collaborate each other. The purpose of this paper is to identify how GIS applications have been in dengue research in Indonesia and to critically examine the issues, strengths, weakness and challenges inherent to those approaches, especially from the spatial analysis and public health point of view. This paper is not to suggest that GIS technology should be used or not be used in dengue research, but to provide some balance by discussing the strength and limitations of GIS in Indonesian context.

Materials and Methods

Searching strategies and databases searched

This review consisted of a search of online published literature in the English and Indonesian language. Databases were searched using keywords contained in the title, abstract, or descriptor terms. The research article was taken by online only using Google Scholar search engine. The search was restricted to studies reported in English or Indonesian-language journals or reports or other publication and indexed with the keyword strategy outlined in Table 1. Databases that were searched included journal web, university database and government office. References within identified articles were reviewed for further studies.

Inclusion/exclusion criteria

Only articles that addressed GIS methodology or dengue–related GIS applications were selected for this review. Each included study had to have: 1) primary research, not article; 2) research that conducted in Indonesia; 3) GIS as a measurement and/or analysis tool and/or application; 4) at least one variable related to the dengue or its vector. The search and review process conducted in October 2013

Systematic review process

The numbers of references searched from Google Scholar database. After reviewing and removing duplicates, references were found of
which 31 were identified following the screening of titles and abstracts. Ultimately, 13 published studies were included in this review.

RESULTS AND DISCUSSION

There were 8 articles in Indonesian language and 5 article in English that contain the combination of three words i.e. Geographic Information System (GIS), dengue and Indonesia in its titles or abstracts. These articles were organized into categories based on the main type of application reported including *dengue risk mapping and surveillance* (*n* = 5), *combined remote sensing-GIS* (*n* = 2), and *climatic and other associated factor with dengue* (*n* = 3). One article organized into 2 categories because contains two type application of GIS.

**DENGUE RISK AREA MAPPING**

There are 5 research using GIS to model dengue risk area. All of them used scoring and overlay. They scored environmental factor and overlay this into dengue incidences map. High risk area represent by high score.

The environment parameter always used in their research were population density, land use, drainage condition, settlement pattern. Another parameter was dengue incidences/reporting cases. Additional parameter was used by Sumunar, Widiyani, and Widiantoro. Widiyani explored about the condition and cleaning water vessel activity related to dengue incidences. Community waste collecting pattern as dengue risk factor parameter was also used in this study. The other additional parameter used Sumunar was rainfall. Different approach was taken by Widiantoro, by using larva and protective factor parameter to developed dengue risk area map.

Despite almost all research in this categories focused on dengue risk area mapping, Apiadsa moved forward by using GIS-dengue risk area map to assisted dengue outbreak management in Magelang. Perdana also have different approach by exploring how GIS can help dengue surveyor officer.

**COMBINED GIS-REMOTE SENSING DENGUE MAPPING**

There are 4 researches using combined GIS-remote sensing technique to study dengue-environment correlation. The 3 researches used satellite image and one research used airplane image (foto udara). Apiadsa and Ruliansyah shown how Quickbird, a very high resolution satellite image can be used as environmental data in GIS-dengue mapping. Kiang using ARIMA to model the dengue cases in Jakarta, Indonesia using TRMM (Tropical Rainfall Monitoring Mission) data and dew point temperature. TRMM is low resolution satellite image. In other hand, Sumunar used airplane image as a data source of her GIS-dengue mapping. Integration of remote sensing imagery and GIS used to analyze physical environmental risk factors associated with dengue such as land use, altitude, rainfall, settlement and mosquito flying area. The research showed that remote sensing image is useful technique to determine physical environment factor related to dengue

**WEB APPLICATION OF GIS-DENGUE MAPPING**

There are only 2 researches on Web application of GIS in dengue research. Hidayatullah developed a simple web GIS-dengue risk area in Tegalrejo, Yogya. A simple information map model not only for health officer but also for residences in that area was proposed. Kusnanto developed a Web-based integrated DHF surveillance in Sleman. This model has made to assist dengue surveillance by health officer.
CLIMATIC AND OTHER FACTOR ASSOCIATED WITH DENGUE

There are only 3 researches in this category. Two research used GIS methodology to correlation between dengue and climatic factor\textsuperscript{14,15}. Astutik\textsuperscript{14} shown the correlation between DHF incidences and rainfall in East Java Province. She also offered 3 model spatio-temporal correlations between DHF incidences and rainfall. Bangs et al.\textsuperscript{15} shown that an ENSO-driven increase in ambient temperature had a marked influence on increased dengue virus transmission by the vector population. He also explored the associations of entomological and climatic effects that precipitated the epidemic before the influx of reported human cases.

Nagao\textsuperscript{16} used GIS to determine geography factor of socio economic that affect DHF Patient in Surabaya He also found that age and socio economic factor affect the mosquito abundance are the most important determinant of the mean age of DHF’s patient.

There are two interrelated components of disease-GIS research. First is disease mapping and the second is disease modeling. Disease mapping is used to understand the geographical distribution and spread of disease in the past or present\textsuperscript{17,18}. Disease modeling extends the disease-mapping application to (a) predict the future spread of disease, (b) identify factors that may foster or inhibit disease transmission, (c) pinpoint high-risk areas for disease prevention or intervention, (d) target control efforts, (e) identify gaps, and (f) increase stimulus for data collection in these areas \textsuperscript{17,18}.

Many factors are known to contribute to dengue transmission, including environmental conditions, socioeconomic status, and meteorological conditions. Among these factors, meteorological and environmental factors are perhaps the most noticeable. For example, dengue transmission may increase with the arrival or the end of a rainy season, and lack of sanitation settlement\textsuperscript{2}. Temperature, humidity and rainfall are the important environmental determinants for dengue transmission\textsuperscript{2}. However, there are only few research in Indonesia focused in this area.

There is only one research on dengue mapping process by a geographer\textsuperscript{10}. Most of the researcher studied GIS-dengue mapping is public health expert or post graduate students so they only studied by plotting incidence to area map. This is the most basic application and involves mapping the incidence/prevalence of dengue over some geographic area\textsuperscript{2}. The focus is on examining past trends as well as the present situation and typically does not include any statistical analysis with the possible exception of correlating dengue incidence/prevalence with population in order to calculate populations at risk. The purpose of these studies is to see the patterns of disease\textsuperscript{2}. GIS overlay technique were used in almost all research, but only 2 researches used additional technique (buffering and clustering)\textsuperscript{6,11}.

There are only 2 researches studied on mapping of relationships between dengue incidence/prevalence and other related variables\textsuperscript{14,15}. The timeframe is still on past trends and the present situation. The goal of these studies is to see if any relationships exist between dengue incidence/prevalence and a host of other variables including temperature\textsuperscript{14,15}, rainfall\textsuperscript{14,15}, land use/land cover\textsuperscript{6,7,8,11}, breeding sites\textsuperscript{8,15} and control programs\textsuperscript{9}. In most cases these studies involve testing to see if any statistical relationships exist.
Astutik has shown a different approach by using complex statistical method modelling, but very difficult to be implemented by health officer in the field. This literature is future-oriented and focuses on predicting areas of dengue risk. Risk models typically use many of the same variables discussed above, but the difference being that statistical relationships are established between dengue incidence/prevalence (the dependent variables) and a range of independent variables in an effort to predict future cases of dengue.

Because data collection is one of the major limitations of using GIS, innovative ways of collecting data are critical to the success of GIS. For the most part, this literature deals with remote sensing in the form of aerial photography and satellite imagery.

The lack of GIS-dengue research in Indonesia showed they are many challenges in GIS-dengue research development. The challenges in using GIS for dengue research can be organized in three parts. The first relates to basic data. Without adequate data, GIS is not very useful. The problems include accurate data on the disease and how it is reported, basic environmental data on land uses, topography, rainfall and demographic data of people. The second relates to technology - specifically computer hardware, GIS software, human resources and training. Based on these data, the biggest problem is only few university have GIS related health expert. This is shown by the fact that 2 of 3 GIS-dengue researches were from Yogyakarta. The third area concerns in methodology development, how can GIS be used to improve our understanding of dengue? As noted, there is no standard methodology in spatial statistical analysis.

There are two potential research areas in GIS-dengue research in Indonesia. They are Disease mapping, especially in geodatabase, GIS assisted surveillance, limited resources GIS mapping and web disease mapping and Disease modeling extends, especially in spread of disease prediction, pinpoint high-risk areas for disease prevention or intervention, target control efforts, identifying gaps and simple model with limited resources.

CONCLUSION

This review explores how GIS approaches have been used to analyze the correlation of dengue incidences with environmental determinants. GIS also used as a tool to improve dengue surveillance and outbreak management. This review revealed the lack of GIS techniques using in Indonesian dengue research.

Instructions to the Authors

Tropical Medicine Journal is a journal devoted to the publication of original articles in all field of basic, tropical medicine and tropical medical biotechnology.

This journal is a journal in tropical medical sciences that used as the media for dissemination of original research, innovative, ideas and new hypotheses in biomedicine, both for medical development, education and application. It also welcomes perspectives articles, biomedical history abridged articles, and reviews.

Statements and opinions expressed in the articles herein are those of author(s) responsibility and not necessary those of the Editor(s), the Faculty of Medicine, or Universitas Gadjah Mada.

Tropical Medicine Journal is published in June and December by the Faculty of Medicine, Universitas Gadjah Mada.

Submission of papers

Articles should be submitted in both hard copy and soft copy forms or in electronic form through e-mails as attachment to: The Editor-in-Chief, Tropical Medicine Journal, Faculty of Medicine, Universitas Gadjah Mada, Sekip Utara, Yogyakarta 55281, Phone: 0274-588483, Fax: 0274-588483 E-mail: tropmedjournal@gmail.com

Basic requirements for articles submitted to Tropical Medicine Journal are: a) original work; b) have not been previously published and not under consideration for publication elsewhere and if accepted will not be published elsewhere; c) should have obtained approval from the Ethics Committee; d) must obtained signed informed consent from subjects for articles involving human subjects.

Referee suggestions

Upon submission, the author should provide one cover letter. In the covering letter, authors should suggest names and addresses (including e-mail) of at least three experts in the field for evaluation of article. The choice of referees will however remain with the editorial board.

Language

Tropical Medicine Journal will publish the articles in English. Editors encourage authors to submit their articles in English. Even so, when a language barrier is encountered, editors allow authors to submit their article in Bahasa Indonesia and it will be translated in English by in-house translator.

Typescripts

Articles should be neatly typed in Times New Roman, 12 pt, double-spaced on A4 format with 3 cm on all margins. Receipt of papers will be acknowledged. Authors will be informed of the referee’s comments.

Article types

Three types of articles may be submitted: a) Original research article (maximum: 25 pages, 35 references); b) Review article (maximum: 40 pages, 100 references); c) Case Report article (maximum: 10 pages, 20 references)
Proofs and Reprints
Proofs of manuscript will be sent to the author for approval prior to publication. Page proofs are considered to be the final version of the manuscript. With the exception of typographical or minor clerical errors, no changes will be made in the manuscript at the proof stage. Corrections should be returned to the Editor within one week. Authors of accepted article will receive 10 free off prints of their articles and can place order for additional off prints or hard copy of the journal after the acceptance of the articles.

Copyright
Submission of an article for publication implies to the transfer of the copyright from the author(s) to the publisher upon acceptance. Accepted articles become the permanent property of Tropical Medicine Journal and may not be reproduced by any means without the written consent of the Editor-in-Chief.

Manuscript preparation
The format of the typescript should be as follows:

a. **Title and authors:** The title should be a brief phrase describing the contents of the article. The title page should include the author’s full names and affiliation that marked Arabic number. The name of the corresponding author should be indicated with postal address, phone, fax and e-mail information.

b. **Abstract:** The author should provide two abstract, in Indonesian and English language. All articles should be provided with an abstract of between 200-300 words in one spacing. The abstract should be written in simple language with structured abstract style. Abstract should describe of the study using below headings: Introduction, Objectives, Methods, Results and Discussion, and Conclusion. Standard nomenclature should be used and abbreviations should be avoided.

c. **Keywords:** A maximum of 5 keywords must be given at the end of the abstract.

d. **Introduction:** The Introduction should provide the problem statement clearly, the relevant literature on the subject, and the proposed approach or solution.

e. **Materials and methods:** The materials and methods should be clear enough to allow experiments to be reproduced. Previously published research procedure should be cited, and important modifications of it should be mentioned briefly. If the conducted research involved the use of human subjects or animal laboratory, it should be stated that the clearance from the Research Ethics Committee was obtained. The Editor may request a copy of the clearance document or informed consent form for verification.

f. **Results and Discussion:** The Results should be presented with clarity and precision and explained without referring to the literature. The original and important findings should be stated. The Results should be illustrated with figures or tables where necessary but these should be kept to the minimum. The Discussion should interpret the findings in view of the results obtained against the background of existing knowledge. The Discussion should highlight what is new in the paper. Any assumption on which conclusions are made must be stated clearly.

g. **Conclusions:** State the Conclusions in a few sentences at the end of the paper.

h. **Acknowledgments:** The Acknowledgments should be presented at the end of the text and before the references. Technical assistance, financial support and advice may be acknowledged.

i. **Tables:** The tables should be kept to a minimum and be designed to be as simple as possible. Each table should be numbered consecutively in Arabic numerals and supplied.
with a heading and a legend. Tables should be self-explanatory without reference to the text.

j. **Figure:** The figures should be numbered consecutively with Arabic numerals. Graphics should be prepared using applications capable of generating high resolution GIF, TIFF, JPEG or Powerpoint before pasting in the Microsoft Word manuscript file. The figures should be constructed in such a manner that they can be understood without reading the text. Appropriate symbols should be used on graphs and explained in the legends. Graphs should not duplicate results presented in tables. Title and comments of the figures and photographs should be provided on separate page using MS Word.

k. **References:** References should be numbered consecutively in the order in which they are first mentioned in the text (Vancouver style). Identify references by Arabic number as superscript in order of appearance. A number must be used even if the author(s) is named in the text. The original number assigned to the reference is reused each time the reference is cited in the text, regardless of its previous position in the text. For example:

```
........ it has been reported¹ ........
........ according to Sardjito² ..........
........ Winestein & Swartz³ conducted .........
........ by Avon et al.⁴ ...........
```

Authors are responsible for the accuracy and the completeness of their references. References should be listed numerically (Vancouver style) at the end of the text and in the same order that they have been cited in the text. For citation references with six or less authors, all authors should be listed, when seven or more authors only first three authors should be listed followed by et al. Journal names are abbreviated according to Index Medicus and Index of Indonesia Learned Periodicals (PDIN 1974). References to journal articles, books, chapters in books, theses, etc. should be listed as given in Sample References.
